TITLE: BACKWASH**TECHNICAL FIELD**

The present invention relates to membrane filtration systems and more
5 particularly, the backwashing of such systems.

BACKGROUND OF THE INVENTION

Porous membrane filtration systems require regular backwashing of the
membranes to maintain filtration efficiency and flux while reducing
transmembrane pressure (TMP) which rises as the membrane pores become
10 clogged with impurities. Such systems usually have a number of membranes in
the form of bundles or arrays of membranes located in a feed tank. Feed is thus
applied to the surfaces of the membranes and filtrate withdrawn from the
membrane lumens. Typically, during the backwash cycle the impurities are
forced out of the membrane pores by pressurised gas, liquid or both into the
15 feed tank or cell. The liquid containing impurities and deposits from the
membranes is then drained or flushed from the tank.

The waste liquid displaced from the tank needs to be disposed of or
reprocessed, usually in an environmentally safe manner, so any reduction in the
volume of such waste liquid is seen as advantageous in terms of environmental
20 impact and cost.

The draining or flushing of the tank, particularly when large arrays of
membranes are used also requires time which results in down time of the
filtration cycle. In order to reduce this down time large pumping systems are
required to quickly drain and refill the tank. Where tanks or cells are arranged in
25 banks and feed is used to refill the tank, a lowering in levels in other cells may

- 2 -

be produced during the refill process. This again impinges on operating efficiency of the filtration system.

Reduction in backwash volume also reduces the volume of chemical cleaning agents required in some systems. This has the two-fold advantage of
5 reducing cost in terms of chemical requirements while also reducing waste disposal problems.

Many filtration systems also employ a gas bubble aeration method to assist in scouring unwanted deposits from the surfaces of the porous membranes during the cleaning stage. In order for such aeration to be effective the
10 membranes must be fully immersed in liquid.

Typically the cleaning process in such systems includes ceasing flow of feed liquid to the vessel in which the membranes are located, continuing the filtration process until the level of liquid in the tank reaches the top of the membranes, aerating the membranes with gas bubbles to scour impurities from
15 the outer membrane surfaces for a period of time, then liquid backwashing the membrane pores. The tank is then drained or flushed to remove the waste liquid containing the impurities dislodged during the aeration and backwashing processes.

It will be appreciated that it is necessary to keep the membranes
20 submerged so as to make the aeration step effective. Adding the liquid backwash at the end of the aeration step results in the liquid level in the tank rising above the membranes. This is "wasted volume" in terms of the requirement of keeping the membranes submerged.

SUMMARY OF THE INVENTION

The present invention seeks to overcome or at least ameliorate this and other disadvantages of the prior art.

According to one aspect, the present invention provides a method of
5 backwashing a membrane filtration module, said module including one or more
membranes located in a feed-containing vessel, the membranes having a
permeable wall which is subjected to a filtration operation wherein feed
containing contaminant matter is applied to one side of the membrane wall and
filtrate is withdrawn from the other side of the membrane wall, the method
10 including:

- a) removing liquid from the feed-containing vessel until the level of
liquid in the feed-containing vessel falls to a first level below an
upper level of the membranes;
- b) suspending the filtration operation;
- 15 c) performing a liquid backwash of the membrane wall until liquid
level within the feed-containing vessel rises to a second
predetermined level above said first level;
- d) aerating the membrane surface with gas bubbles to dislodge
fouling materials therefrom;
- 20 e) performing a sweep or drain down of the feed-containing vessel to
remove the liquid containing the dislodged contaminant matter;
and
- f) recommencing the filtration operation.

Preferably, the second predetermined level is selected such that the liquid
25 level rises at least to the upper level of the membranes during the aeration step.

- 4 -

Preferably, the flow of feed into the feed-containing vessel is suspended prior to removal step a). For preference, the removal of liquid is achieved fully or partially by the filtration process. Preferably, in a pressurized filtration system, a pressurized gas is employed during the filtration process to push the liquid from
5 the feed side through the permeable membrane wall during the removal step a). The aeration step may commence prior to removal of liquid step and continue until the sweep or drain down step e).

This process has the advantage of reducing the backwash volume. Also, rather than filtering down to the required liquid level, it is possible to drain or
10 pump away liquid in the feed-containing tank to achieve the same result. This has the advantage of not increasing the flux of the membrane during the filter down step, and can be done quickly to reduce filtration down time. The drained feed may be returned to the inlet of the filtration plant so as not to be wasted, or transferred to other tanks operating in parallel.

15 In an alternate method, the filtration step may be done at varying filtrate flows; the flow being adjusted to maintain a constant transmembrane pressure (TMP) as the liquid level drops down the membranes.

The TMP may be monitored during the removal of liquid step and used to determine when the liquid level has dropped below the top of the membranes, or
20 how far below the upper level of the membranes the liquid level has dropped. This is possible because as more of the membrane is exposed the filtration area is less and the TMP will increase. TMP will also increase due to the fact that more of the filtrate flow travels further along the lumen so increasing the lumen pressure drop (assuming the flow is kept constant and filtrate is being withdrawn
25 from the upper end of the membrane lumen). Accordingly, the change in TMP

- 5 -

may be used to monitor the liquid level in the feed tank before commencing the liquid backwash step. This may also be used to adjust the filtrate flow and maintain a constant TMP so avoiding significant changes in the flux on the remaining filtrate area. Alternatively, such a method can be used to control to
5 the TMP to any desired predetermined level, for example, it may desirable to lower the liquid level in the feed-containing tank, keeping the TMP at the maximum allowable TMP, say 85 kPa.

BRIEF DESCRIPTION OF THE DRAWINGS

A preferred embodiment of the invention will now be described, by way of
10 example only, with reference to the accompanying drawings in which:

Figures 1a to 1e show schematic views of the membrane module at various stages of the backwash process according to an embodiment of the invention.

DESCRIPTION OF THE PREFERRED EMBODIMENT

15 Referring to the Figures 1a to 1e, an illustrative embodiment of the invention is described. The filtration module 4 is mounted within a housing vessel 3 which contains the feed to be filtered. The filtration module 8 contains a bundle or bundles of hollow fibre membranes 5 extending between upper and
20 lower headers 6 and 7, respectively. The lower header 7 is provided with a number of openings 9 communicating with the interior of the fibre bundle and an inlet port 10. Feed is supplied through port 11 under the control of valve AV1.

Permeate/filtrate is withdrawn through chamber 12 and line 13. A liquid backwash may also be applied through line 13.

25 Figure 1a shows the module in normal filtration operation with the liquid level in the vessel 3 at L1 covering the upper header 6. When the backwash

stage is to be commenced, in this embodiment, the flow of feed is stopped by shutting valve AV1. Filtrate continues to be withdrawn through the fibre lumens and chamber 12 and line 13. The level of liquid in the vessel 3 falls, as shown in Figure 1b, to level L2.

5 Once level L2 is reached, a liquid backwash is commenced by flowing liquid back through the fibre lumens and walls via line 13. This results in the liquid level again rising in the vessel to L1 as shown in Figure 1c. An aeration step is then commenced by feeding gas through port 10 and openings 9 as shown in Figure 1d. In another embodiment, the liquid level resulting from the
10 liquid backwash may be just below level L1 such that level L1 is reached during the aeration step with the liquid level rising further as a result of bubbles present in the liquid. A similar result may be achieved by commencing the aeration step during the liquid backwash.

 Once the aeration step is completed the vessel is swept or drained as
15 shown in Figure 1e to remove dislodged waste materials accumulated in the vessel liquid. Following this step feed is reintroduced to the vessel by opening valve AV1 and filtration recommenced.

 Although the embodiment relates to vertically orientated membranes, it will be appreciated that the invention is not limited to such an orientation and the
20 membranes may be orientated in any desired position or configuration.

 It will be appreciated that the invention may be applied to both pressurized and non-pressurized systems where the feed-containing vessel is open to atmosphere.

- 7 -

It will be appreciated that further embodiments and exemplifications of the invention are possible with departing from the spirit or scope of the invention described.

CLAIMS:

1. A method of backwashing a membrane filtration module, said module including one or more membranes located in a feed-containing vessel, the membranes having a permeable wall which is subjected to a filtration operation
5 wherein feed containing contaminant matter is applied to one side of the membrane wall and filtrate is withdrawn from the other side of the membrane wall, the method including:
- a) removing liquid from the feed-containing vessel until the level of liquid in the feed-containing vessel falls to a first level below an
10 upper level of the membranes;
 - b) suspending the filtration operation;
 - c) performing a liquid backwash of the membrane wall until liquid level within the feed-containing vessel rises to a second predetermined level above said first level;
 - 15 d) aerating the membrane surface with gas bubbles to dislodge fouling materials therefrom;
 - e) performing a sweep or drain down of the feed-containing vessel to remove the liquid containing the dislodged contaminant matter; and
 - 20 f) recommencing the filtration operation.
2. A method according to claim 1 including selecting the second predetermined level such that the liquid level rises at least to the upper level of the membranes during the aeration step.
3. A method according to claim 1 or 2, wherein the flow of feed into the feed-
25 containing vessel is suspended prior to removal step a).

- 9 -

4. A method according to any one of the preceding claims wherein the aeration step is commenced prior to removal of liquid step and continues until the sweep or drain down step e).
5. A method according to any one of the preceding claims wherein the
5 removal of liquid is achieved fully or partially by the filtration process.
6. A method according to claim 5 including applying a pressurized gas to the liquid on the said one side of the membrane wall to push the liquid through the membrane wall during the filtration process.
7. A method according to any one of claims 1 to 4 wherein the removal of
10 liquid is achieved by drain down of liquid in the feed-containing tank.
8. A method according to any one of claims 1 to 4 wherein the removal of liquid is achieved by pumping liquid from the feed-containing tank.
9. A method according to any one of the preceding claims including the step of returning the removed liquid to the feed-containing vessel when filtration is
15 recommenced.
10. A method according to any one of the preceding claims including the step of returning the removed liquid to the feed-containing vessel of a further filtration system.
11. A method according to anyone of the preceding claims including the step of
20 varying filtrate flow from membranes to maintain a substantially constant transmembrane pressure (TMP) across said membranes as the liquid level is reduced within the feed-containing vessel.
12. A method according to claim 11 wherein the transmembrane pressure is maintained at or below a predetermined value.

- 10 -

13. A method according to any one of the preceding claims including the step of monitoring the transmembrane pressure across said membranes to determine the level of liquid in said feed-containing vessel.

14. A method according to claim 13 wherein said monitoring step is performed
5 during the removal step a).
